

12.8 FINAL THOUGHTS

You have just taken a tour through the exciting world of AI-assisted coding. From understanding how AI can supercharge your development process to building a to-list app with ChatGPT, you have covered quite a bit of ground.

You touched on best practices, like bringing in AI for assistance, not replacement, and why clear and specific prompts are warranted. And neither did you skirt the issues—prominently, the huge concerns for data privacy and the potential creation of overreliance on automation.

It's one thing to read about it and another thing to experience it. So, you should try this.

Whether you're a seasoned developer or have never written a code, AI tools have something for everyone. They can assist in writing code faster or learning new languages and even demonstrate the skills to build simple applications from scratch on their own.

Here, your goal should not be to build something great but to understand the capabilities of these AI tools. So, start with a simple project like a calculator app and see how AI can help you bring it to life. Experiment with different tools like ChatGPT, GitHub Copilot, or Codeium. Play around with prompts, and see what works and what doesn't.

Langflow – Explore how to visually build and deploy AI-powered agents with no code using Langflow in this video.
