

Some of the measures organisations can take to ensure fairness and avoid bias are:

1. Bias audits

You must regularly conduct bias audits to help identify and mitigate biases in AI systems. These audits should analyse training data and AI outputs for discriminatory patterns. Once such flaws are recognised, they should be dealt with accordingly.

If the training data included biased content, such content must be removed before the training begins. If the model produces biased outputs, the source of the bias in the training data must be identified and deleted, and then, the model must be re-trained.

2. Diverse Data Sets

You deal with bias by providing representation for every segment of society. Similarly, when building gen AI systems, organisations must use diverse training data that accurately represents all voices equally. This will help minimise biases and promote fairness. This should ensure that the AI model does not disproportionately affect certain groups.

3. Fairness Metrics

Organisations can develop fairness metrics to smoothen the process of bias audits. This will ensure that the AI models operate equitably. These metrics should be monitored continuously, and organisations must strive to improve them.
