

4.2.1 Complete

The legacy version is the older version of the OpenAI Playground application. Through this, you will understand why the ChatGPT is a probability model and not anything else. You can play around with parameters like model, temperature, maximum length, stop sequences, and top P.

You can even choose the ChatGPT model you want to get the response from. In this case, you will be using gpt-3.5-turbo-instruct, but there are two more models called DaVinci-002 and Babbage-002, which were the older models of ChatGPT.

Note - OpenAI Assistance legacy version is being discarded

The temperature parameter controls the randomness of the responses. The lower the temperature, the more accurate the response, and the higher the temperature, the higher the model's creativity and inaccuracy.

So, if you need creative writing, go for a higher temperature. If you want more precise answers, go for a lower temperature. If you want the most suitable answers for your prompts, then go with temperature as one.

By default, the temperature is set as one. If you keep it too low, the bot will not have the memory and time to craft the desired response. If you keep it too high, it will start hallucinating and give loose responses. In all honesty, one is the ideal temperature.

The maximum length parameter lets us choose the desired length of response. By default, this is set to 256 tokens, each with roughly four characters. So, the maximum length will be about 1,024 characters. This should be approximately 200 words.

A stop sequence makes ChatGPT stop generating the response at a desired point.

Top P is a parameter that controls the diversity of your content. It essentially means the amount of risk your model will take to generate new content. If we take a high top P, the model will generate more repetitive content.
