

Conversely, if it takes a low top P, the model will generate less repetitive content from a diverse range. So, the higher the top P, the higher the repetitiveness and vice versa. To balance things out, we keep it at the mid-value of 0.5.^[1]

The frequency penalty parameter sets the severity of penalties on new tokens based on their frequency in the text. A high-frequency penalty makes the content less repetitive and vice versa.

Other parameters include presence penalty, best of, inject start text, inject restart text, and show probabilities.

When we set the show probabilities parameter to the full spectrum, you can see the response itself and what other words ChatGPT considers using in its place.

Let's take a prompt's example, "What is generative AI?"

The response you would get is:

High-Probability Word Was Chosen

Lower-Probability Words Were Chosen

What is Generative AI?

Generative AI, also known as generative adversarial networks (GANs), is a type of artificial intelligence (AI) that uses machine learning algorithms to generate new data or content that is similar to the input data it was trained on. It works by pitting two neural networks against each other - a generator network that creates new data and a discriminator network that evaluates the generated data and provides feedback to the generator. Through this process, the generator network learns to create increasingly realistic data, such as images, text, or music, that can be used for a variety of applications, including art, design, and data synthesis. Generative AI has the potential to create highly realistic and diverse outputs, making it a powerful tool for creativity and innovation.
