

What is the Master Mind? I visualize the Master Mind as a formless, boundless reservoir of thought-vibration. Not all of it can be available to any one person at any one time. When you are in harmony with another person or with a number of other people, however, the attunement of mind to mind results in a "tuning in" of incalculable value. A man who has a corps of assistants with whom he maintains amiable relations has at his disposal far more than the knowledge his assistants may give him by obvious means. Their minds constantly feed his through mental broadcast power, and receive information from his mind as well. The same is true when friends or business associates form a Master Mind group at which they discuss various topics or problems. Their several minds focused on the topic obviously add great power to the mind most occupied with it; but also an exchange of broadcast thoughts is effected right then, and also later, when the persons involved may be far apart. This is not obvious as is speech or writing, but its power goes beyond anything science can completely explain.

I have been greatly interested in observing how the science of this atomic age gives "faith and credit" in this direction to the science of fifty years ago. At that time we could list eighty-odd forms of physical matter (we list many more now) and we knew that matter is made of incredibly tiny particles with space between. We had begun to know there is so much space within matter that, in a sense, nothing is "solid." You and I, the desk at which I write, my typewriter, this dot (.) are made of atoms; the atom in turn contains electrons which either revolve in orbits or vibrate rapidly to and fro. Other particles such as neutrons are now postulated, but the principle remains the same. Whether you observe the largest star that glitters in the sky or the smallest grain of sand among billions on a beach, it is a collection of particles, space and electric charges.

Fifty years ago we had begun to have some proof that even the most minute particles are not "things" but bundles of vibrations. We knew, too, that various forms of energy proceed through air and space in their characteristic forms because of their varying frequency of vibration. Thus, vibrations beginning at about 15 per second and going up to about 15,000 per second are perceptible to the human ear as sound. Above that we no longer hear vibrations; but at around 1,500,000 vibrations per second that form of energy called heat begins and we can feel it with another of our senses.

Higher up the scale of vibration comes light, often com-
