

What constitutes abundance? You know by now it is a relative term. Surely one who does not have enough to eat can not be said to enjoy abundance; but there are those who do not believe they are wealthy until they can eat their meals from golden plates. Be wealthy in your own way and you will know that you are wealthy . . . and bear in mind that even a beggar enjoys the beauty of the earth, the drift of white clouds and the sight of a rainbow or a twinkling star.

This is a practical book nevertheless, and I am sure you have noticed that I do not suggest any outright substitute for sufficient money. Let us look again at the question of sufficiency; let us look at its very beginnings.

Wealth comes to the man who can see a potential for wealth. I was brought up on something we called a farm. Well, it was land, all right, and one could observe certain crops growing in the fields and certain animals grazing. A good, efficient farmer would have noticed, however, that a good deal of our "farm" wasn't a farm at all. It included too much untilled land which produced the need to pay taxes, but no food to be eaten or produce to sell.

We lacked training, we lacked capital and we lacked quite a few other things—but still I do not quite know why we let a potential for (relative) wealth lie there without being used. It wasn't till years later that I heard about scientific farming which can produce more income from ten acres than my father could have produced from a hundred acres of equivalent land. Recently I met a truck farmer who makes a splendid living from only five acres by scientific rotation of his crops—and I knew I had met a man who could see and use his wealth-potential.

Notice, however, that the farmer's *basic* wealth-potential is not in his land. It is in his mind—in his willingness to learn good farming methods and use them, or, going even farther back, in his willingness to learn what constitutes good farmland and make sure he gets it.

A recent newspaper item mentioned that in some parts of Africa, today, it takes eight people to grow enough food crops to feed nine people. Fortunately, good farming methods are spreading across the world along with good farming machinery, and modern fertilizers can do wonders with poor land. Yet when the same eight dirt-scratchers are turned into eight tractor drivers planting pedigreed seed, and their labor feeds eight hundred or eight thousand—still, first, their minds
