

Retirees clearly would have been harmed historically by having their emotions lead them to deviate from their strategic asset allocation. This is an important consideration, because to the extent that individuals do not successfully stick with an asset allocation over time, the hypothetical retiree used to derive the 4 percent rule is irrelevant to real individual outcomes. To the extent that advisors can help retirees better approach the ideal outcomes for the hypothetical retiree used in safe withdrawal rate studies, the discussion of portfolio performance falling below a benchmark return should generally not be interpreted as an impact of advisory fees. Without the better outcomes supported by advisory fees, retirees may be left in an even worse position.
