

Exhibit 7.20 provides the corresponding analysis showing the distribution for asset allocation over time, along with the stock allocation paths for twenty random simulations. We can observe clearly how this strategy pushes the stock allocation higher than the other strategies, since it leads to the bond ladder depleting prior to the growth portfolio. The stock allocation at the tenth percentile rises almost immediately as well, unlike in the other cases. The median stock allocation continues to rise, surpassing 80 percent within the first ten years of retirement.
